## General introduction

This 2007-1 publication is mainly devoted to analysis of the evolution in the offer and demand for transport capacity in 2006. The demand for transport capacity is based on an approach to the transport carried out on the four main European routes, by family of goods. It has to be said that full data for 2006 and 2007 is not available until quite some time after the reference period. This situation should change from 2008 onwards with the entry into force of the Regulation (EC) Nr 1365/2006 on monitoring freight transport. These regulations will have the advantage of providing harmonised data, which will therefore be more readily comparable and usable.

The approach to transport by family of goods and by main routes should make it possible to produce an analysis by industrial sector in context, with forecasts for the evolution of demand for transport capacity from a given industrial sector, taking its potential into account.

It also makes it possible to follow the evolution of the modal split of inland waterways transport compared with other modes of transport. In the present context, it is above all in the field of containers in sea and inland ports that this exercise is possible.

In this publication, the offer of transport capacity is, as usual, estimated on the basis of data on the national fleets. For the first time, it has been possible to take into account data on the fleets of most of the Danube States and the States in eastern Europe. It would appear nevertheless that it remains a somewhat delicate exercise to reach an exact estimate of the potential European fleet, in that the criteria applied are not always harmonised. It will only be possible to envisage a totally reliable view of capacity available on the European network when common bases for vessel registration have been set up.

Until this happens, monitoring new vessels constitutes a major indication of the evolution in the offer of transport capacity, particularly in a context in which break-ups remain the exception and inter-State transfers have no effect on the overall capacity available on the market. Analysis of the characteristics of the vessels brought into service provides information on the evolution of the fleet.

# Chapter 1

## Analysis of demand for transport capacity

### 1. Evolution of economic growth in Europe

It is a fact that the evolution of all modes of transport is closely linked to economic development. Increased economic growth among shippers is reflected in an increase in demand for transport. As a result, despite a degree of flexibility, demand for transport depends on the growth or slowing down of the economy. It is possible to observe, however, that demand for transport sometimes reacts more quickly and may anticipate an acceleration in general economic growth. It is therefore important to observe the evolution of both the economy and transport services, on different scales and for specific sectors.

Although world economic growth began to slow down slightly in 2006, it nevertheless remained at a high level in Europe in 2007. It was above all in the United States that the slowing down was noticeable.

In July 2007, the financial markets experienced some turbulence when it transpired that low-quality mortgage loans had generated substantial losses for a good number of banks. This crisis in the property market affected the evolution of the GDP in the United States and resulted in the stagnation of consumption, which was further fuelled by high oil prices. The employment market evolved in a steady and even positive fashion, particularly in the first half of the year. External demand remained sustained in the United States because of the dollar's weakness against the euro.

The emerging economies of south-east Asia once again made this the most dynamic region, with China in the lead. China's GDP increased by 11.5% in the first half of 2007. The country's productivity is increasing strongly, and both investments and exports have seen impressive growth. 2007 was the first time Asia exported more to Europe than to the United States.

The fact that the price of oil on the world market has evolved at high levels is a consequence of the clear increase in consumption which is the result of the strong growth in the global economy (particularly in India and China). In November 2007, the price of oil reached an absolute record level. As the OECD countries are showing greater interest in bio-fuels, the OPEC countries have not deemed it worth making any new investments rapidly. As a result, the world market for oil remains structurally narrow. It has also been influenced by financial difficulties.

Graph 1

In the euro zone, economic growth was higher than the general world trend, particularly during the first half of 2007. According to the elements available at present, average growth in GDP of the EU-27 was 3% in 2006 and 2.9% in 2007. Domestic demand, exports and investments have been the driving forces behind this economic growth, which has progressed slightly less rapidly than during the previous periods. This slight slowing down is explained by the exchange rate between the euro and the dollar, the high level of oil prices, and the stagnation of American demand. In Europe, the services sector and to a lesser extent the industry sector continued to act as a driving force for growth. Exports out of the euro zone continued to make progress (taking advantage of trade with emerging countries), as did investment and employment. Towards the end of the year, there was an increase in inflation in the euro zone, resulting mainly from the oil bill. There are substantial regional disparities in Europe. In the new Member States such as Poland, Slovakia (production of cars) and the Baltic States, growth is substantially higher than the European average. It is accompanied by considerable movements of imports and exports. The economy of the Rhine countries also showed sustained growth, although the rate of progress was slightly less than in 2006. Compared with 2006, the growth rate was 0.1% lower in France, 0.3% lower in the Netherlands, and 0.4% lower in Germany. On 1 January 2007, the VAT rate was increased in Germany, and this had the immediate result of slowing consumption during the first half of the year. 2007 was nevertheless a globally favourable year for Europe, although it did not see the peaks of growth observed in 2006. The high level of economic growth that marked the end of the 1990s was nevertheless achieved once more.

Sources: CPB, Eurostat

## GENERAL OBSERVATION OF QUALITY

The economies are increasingly interdependent and are becoming networked economies, based increasingly on specific competences and services. Nevertheless the role of transport remains of capital importance and reflects the mechanisms that are characteristic of the modern international economy – globalisation, division of labour, economies of scale, and specialisation in production. Although the cost of transport is relatively low compared with the global costs of production, these latter have been a contributing factor in the evolution. Containerisation has made the markets of western Europe more accessible for the Far East. Sea ports in Europe are consolidating their position and are continuing to expand the prospects for growth in world trade. In this context, massive investments have been made in the container market, where mechanisms are not the same as in other markets, particularly the market for bulk transport. Bulk transport in Europe features firstly constant deliveries to a small number of major customers (for example, power stations and smelting plant). The container market, however, is characterised by its complexity and the management of the logistics chain. Generally, containers are not used for raw materials but rather for finished or semi-finished products. As competition is fierce in the container market, flexibility and the integration of management in the logistics chains are essential. The goods need to be delivered exactly on time, because the manufacturing processes are being developed with an increasingly high level of precision, with shippers keen to keep stocks to a minimum, inter alia. As a result, the reliability of transport is of capital importance, as any delay represents a loss for the shipper. It is in this context that the various modes of land-based transport, including transport on inland waterways, must build up their offer of transport. On a market where competition is fierce, particularly in terms of prices, there are nevertheless ways of ensuring differentiation. While transport on inland waterways aims to continue to serve the “gateway concept”, it should aim for effectiveness and meet the shippers’ expectations. It is not enough to offer capacity – the flexibility and reliability of the services are also becoming increasingly important. The advantages of transport on inland waterways are well known – substantial capacity and attractive prices. But it also has disadvantages, including the frequent necessity for additional transshipment. The inland waterways transport sector increases its chances with innovation and communications systems such as the RIS. Shippers using the container market are expressing considerable interest in the immediate traceability of each part of a cargo – this data constitutes the basic information for managing their operations. Paying particular attention to certain aspects such as security which improves transport conditions also helps optimise the microeconomic situation of the shippers. Other elements, beyond the sector’s sphere of influence, may constitute a threat for the market share of inland waterways transport. These include reduced access to inland ports, and delays in handling at sea terminals. All this calls for constant vigilance.

## 2. Evolution of prospects for demand for transport capacity

### 2.1. OVERALL EVOLUTION OF FREIGHT TRANSPORT

As described above, world trade increased in 2006 and in 2007 in direct relation to the favourable context of the economy. Perfectly logically, it produced an increase in the transport of goods, despite the increase in oil prices. The delocalisation of production towards regions where labour is cheaper – and not only Asia – is the main reason for the growth in transport, particularly of containers. In the field of container transport, China has been the most important connection for the ports of Rotterdam (which also sees substantial intra-European traffic) and Hamburg (with 15 and 30% of volumes in 2006 respectively). China was also a destination for exports, further to its economic development (since 1999, it has seen its commercial activity increase on average by 20%). The strong growth of transport is therefore obvious in the container sector. Other openings on world markets – as a result of the breaking down of commercial barriers – will increase trade, and container traffic as a result. Thus, according to the FEFC (the authoritative federation of shipping lines), 2007 was a very favourable year (with an 18% increase in container traffic) and the prospects for 2008 look to be similar. Despite the enormous volumes available to sea shipping lines, they have difficulty in making operation profitable. The market changes constantly (take-overs, mergers, compression of expenditure). The consolidations and economies of scale produced by the concentration of the offer have been to the advantage of all the intercontinental routes. Thus observation of commercial traffic shows clearly that shippers often opt for using several ports (multi-porting) in Europe for strategic reasons, rather than selecting a main port. By choosing to dock in Europe, they influence the distribution of transshipments in the sea ports, which in turn has an impact on distribution set-ups throughout Europe.

The growth of world trade has potentially had the effect of increasing demand for transport in Europe. Transport on inland waterways, which is particularly suitable for large quantities, also profits from this. The increase in container transport is an opportunity for those countries with European ports, not only because of the volumes to be transported, but also because of the associated logistics of enhancing the value of the goods and the resulting positive impact on the offer of employment. For the EU, transport and logistics are important factors in economic development and as a result will therefore be facilitated wherever possible. On the other hand, in the policy on freight transport, external costs linked more particularly to pollution are increasingly decisive in addition to the development of volumes. Methods that make progress in this area have much better chances in the long term. However, cost and quality at present remain the determining factors in competition in the transport sector. As a rule, container transport at the national level (proximity) is mainly by road, although transport on inland waterways has managed to occupy a strong market position for international (i.e. longer) routes. The pre-requisite for river transport is obviously the existence of suitable waterways. Competition between road transport and inland waterways transport is mainly evident in the market for packages, over medium distances. One potential threat to the reliability of transport by rail and inland waterway is its vulnerability as a concentrated route. On the other hand, the roads are congested on key links in the network, which causes increasing economic losses. Rail transport has new capacity for the transport of goods in Europe as a result of the capacity released onto the network by the creation of high-speed lines for passenger transport and the improvement in the management of traffic at the national level. International interoperability,

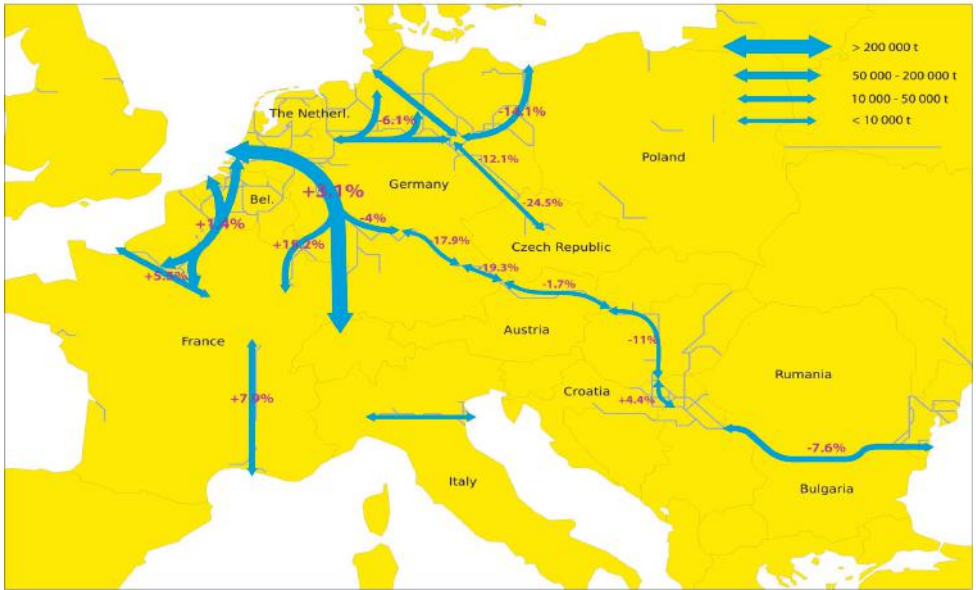

which is sometimes lacking in freight transport by rail, is making progress.

A forecast study of transport traffic in Germany in 2025 shows that all the modes of transport will benefit from the sustained growth of freight transport, but that the major beneficiary will be road, despite all the measures aimed at promoting rail and inland waterways and the increase in distances travelled. Nevertheless, transport by rail should increase more than transport on inland waterways.

This forecast study shows that until 2025 the transported volumes between the seaports (ARA and North-See) should grow about 6.3% for the containerised goods and about 2.4% for the not containerised goods. The difference between these two growth rates will lead to an increase of the share of the containerised goods which will raise from 35.6% in 2004 to 55% in 2025.

Main transport flows of the inland navigation in Europe

## 2.2. Freight transport using inland waterways

### 2.2.1. Main European routes

At the European level, there are four main transport routes, shown on this map:

- the Rhine route, which represents more than 63% of the volume transported in Europe. As this is a river route developed long ago, the increase in the volume transported is relatively slow, but structural. It reflects the development of an industrial fabric that has been in existence for a long time. Only the container sector has seen sustained progress over the past decade;

Graph 2

- the north-south route between France, Belgium and the Netherlands, which represents about 15% of volume and is in a development stage that will be further reinforced by the opening of the Seine-Nord Canal. This route has been making considerable progress, particularly for trade traffic between France, Belgium and the Netherlands. It should nevertheless be borne in mind that this progress is on the basis of volumes that are still relatively small, although their potential remains substantial;
- the east-west route in Germany, linking eastern Europe and the North Sea ports to the industrial fabric of the Ruhr, representing slightly more than 4%. This route is based mainly on trade between the Ruhr region and the area between Berlin and the Elbe, and on the river traffic for trade with the German sea ports;
- the Main-Danube route, which represents about 10% and is in a development phase at the same pace as the industrial fabric of the States bordering the Danube. Given the length of this route, most of the traffic is inter-regional or international, although not all goods are transported the entire length of the route. This aspect will be broached in the following paragraph.

These routes mainly represent international traffic, apart from the east-west route, on which a large proportion of the traffic does not cross any frontiers.

2006 saw progress in traffic on the north-south route and on the Rhine, although there was a decrease in volumes transported on the east-west route and on the Danube as a whole.

### **2.2.2. Regional and inter-regional transport**

#### *Seine Basin*

The Seine Basin continued its development in 2006, with progress in the order of 5.5% of transhipped volume. The goods for which volume progressed the most were containers and products connected with construction and public works. Data for the whole of 2007 is not yet available, but it should indicate the continuation of this trend, in the light of the economic context observed.

#### *Belgium*

In view of the structure of the Belgian river network and the relatively short distances involved, the evolution of domestic transport in Belgium may give indications as to the position of this mode of transport in the country. In view of the state of the rail network in the country, there has been an increase in the market share of transport using inland waterways compared with rail, particularly in recent years. In 2006 the volumes transported as domestic traffic on inland waterways increased by 6%, compared with just 2.7% for international traffic.

#### *Netherlands*

The Dutch river network is even denser than Belgium's, and justifies separate analysis. Transport on inland waterways has always occupied a large share of the market. In 2006, the volumes transported by inland waterway decreased by almost 2%, while international traffic increased by about 1%. Overall, this resulted in a stagnation of volumes despite a favourable economic context and sustained transshipments in the sea ports. Along with road transport, it is without doubt rail transport that has increased its market share during the past year, particularly with the opening in 2007 of the "Betuwe Route". This trend should continue in the coming years.

#### *German network (excluding the Rhine)*

Transport in the Elbe region was affected by the irregularity of the water conditions. There is considerable potential nevertheless, particularly for the container sector in contact with the sea ports of northern Germany, where the volumes handled continue to increase. In the present context, transport on inland waterways benefits from this since the volumes transported in this sector increased considerably in 2006, although there are still certain infrastructural hindrances, particularly upstream of Magdeburg, which has the potential to become an important hub in the future.

#### *Upper reaches of the Danube and Canal*

In terms of transport both between the Main and the Danube via the Main-Danube Canal and on the upper reaches of the Danube, 2006 was marked by a substantial decrease in the volumes transported. This decrease was above all the result of hydrological phenomena, including the canal being blocked by ice for a long period and irregular water conditions,

particularly periods of low water in the summer. It would appear that water conditions were more abundant in 2007, but at the time of the present publication the full figures for volumes were not yet available.

## **2.3. Approach to demand for transport by sector**

*Preliminary remark:*

For each sector served by transport on inland waterways, there is a map describing the situation of the main flows of goods transport in Europe, and the figures for evolution of the flows in 2006 compared with 2005.

### **2.3.1. Agricultural sector**

*General situation of the sector*

For 2008, an increase in exports of wheat is expected, in view of the low level of stocks on world markets, due to poor harvests in certain areas. In western Europe, the 2007 harvest was considered relatively satisfactory, comparable to the 2006 harvest, and this is why an increase in demand for the transport of wheat may be expected in 2008.

The transport of foodstuffs and animal feed progressed by almost 6%. This growth was mainly due to growth in the transport of oleaginous plants and cattle feed, which represents more than 80% of this market. The level of demand should remain sustained in the short term.

### Transport flows generated by agricultural products

Over a six-year period (2000 – 2006), the following trends may be observed:

- a relative stagnation in the volume of wheat transported in western Europe,
- a clear decrease in the transport of fertilisers, with -28% for chemical fertilisers, resulting from the more reasonable use being made of them,
- a 30% drop in the transport of wood, which may be conjunctural, as the volumes resulting from the storm damage have now been absorbed, although at the same time supply purchasing is again beginning to keep demand buoyant (cf. evolution in 2004),
- progress of more than 6% in oleaginous plants in connection with the use of bio-energies.

The graph below shows the breakdown of market shares representing the various agricultural products.

Graph 3

*On the Rhine*

Although the transport of fertilisers stagnated in the first half of 2007, the transport of agricultural products progressed by almost 1%. The transport of cereals, which constitutes about 80% of this category of goods, decreased slightly. The 20% drop in the transport of wheat, which represents about half this category, was not entirely offset by the increase of about 20% in the transport of barley and maize. The increase in traffic in this category was essentially due to the tripling of volumes of wood transported (which now represents 12% of this market).

*North-south*

On the north-south route, the transport of agriculture-related products, which represents about 11% of all the transport on this route, stagnated in 2006. Detailed elements are not yet available for 2007, but it is expected that there will have been a slight increase in the volumes transported on this route.

*Danube*

On the Danube, the transport of agriculture-related products decreased noticeably in all the States concerned. This was particularly true on the upper reaches of the Danube, where this segment represents a large proportion of the volumes transported (40 to 50%), where the decrease was the greatest (a reduction of more than 20% on the Main-Danube route).

*Elbe*

This type of transport also decreased considerably on the Elbe market, as did traffic overall, mainly because of a lack of confidence on the part of shippers because of water conditions;

as a result, shippers tended to turn away from this market and use other German inland waterways less subject to low water conditions.

### **2.3.2. Iron and steel sector**

#### *General situation of the sector*

Imports of steel into Europe progressed over the first six months of 2007, in part in order to cover the requirements generated by those States which recently joined the European Union. According to professionals in the sector, there has been a pause since the third quarter of 2007. This is not, however, a result of a reduction in stocks, which had become excessive in the course of the first half of 2007. In 2007 as a whole, the German iron and steel industry achieved a new record level, with an increase of 2.5% in the production of unprocessed products.

Experts on this sector estimate that further to this period of rationalising stocks, activity in this sector should resume its previous pace in 2008, particularly under the effect of the world and European economic situation which is still favourable for this sector. There are nevertheless certain areas of uncertainty which have appeared in recent months, and these could temper this optimism somewhat. Thus it may be noted that the resumption of activity in the construction and public works sector in Europe has also contributed to keeping domestic demand buoyant in Europe. It remains to be seen how demand from this sector will evolve in the coming months, in view of credit arrangements. The European iron and steel industry also fears an increase in imports of cheap products to the detriment of European production. In the medium term, the present level of the euro is also likely to be damaging to exports.

#### *River transport*

For transport on inland waterways, demand for transport remains high, whether for imports or exports. On the Rhine and on the Moselle, where the transport of products in connection with the iron and steel industry represents almost 25% of the volumes transported, the latter progressed by 1.9% on the Rhine and by 17% on the Moselle. During the first half of 2007, the transport of metallurgical products progressed on average by 23% by volume in comparison with the first half of 2006. The transport of ore and metallurgical scrap progressed by barely 3%. For these two categories of goods, it was transport upstream mainly resulting from the flow of imports that progressed strongly. Looked at more closely, this concerned semi-finished products such as sheet steel. The first data available on transport on inland waterways for the whole of 2007 indicates substantial rates of progress for volumes transported into and out of the sea ports (e.g. in the port of Antwerp, +11% for raw materials and +24% for metallurgical products). Demand for steel remains high in global terms, and this should ensure maintenance of demand for transport on European inland waterways in 2008.

Transport flows generated by Iron and steel products

Graph 4

Types of metallurgical products transported in 2006 by inland waterway in the in Europe

### **2.3.3. Energy sector - coal**

Germany is the biggest importer of coal among all the Rhine countries, and indeed among all the countries of the EU. It uses mainly coal to produce electricity, whereas other countries often use nuclear power and natural gas. Another factor is that the German iron and steel industry is the most important in the European market. Despite German domestic production, about two-thirds of the market for coal is supplied by the various European sea ports (2006: 46.6 million tonnes, 2007: about 43 million tonnes). For strategic reasons, Germany imports its coal from a number of suppliers. Poland and South Africa were already important suppliers, and recently South American and Indonesia have also seen their market shares increase. Although, according to 2006 figures, the ports of Hamburg and Le Havre play a not inconsiderable role in these imports, Rotterdam (33%) and Amsterdam (24%) are much more important, as are Antwerp (11%), Dunkirk (12%) and Hamburg (6%), although to a lesser extent. According to the data, Germany is the main destination for incoming coal (about 80%), transiting mainly through the ARA ports.

In the first half of 2007, the volumes of coal transshipped in Rotterdam decreased by 1.5 million tonnes (-11%), which was the result of a mild winter and maintenance work at a major electricity power station. There are similar reasons for the decrease (-8%) in the volumes transshipped in Antwerp (8.6 million tonnes), for data calculated over the year as a whole. Transport on inland waterways saw a reduction of 4.8% in transport into the hinterland. Contrary to the data for Antwerp, Rotterdam finally recorded progress for 2007. Incoming goods progressed by 0.9%, so that 28 million tonnes were transhipped in 2007. Transshipments in Le Havre increased by 34%, reaching the 2.4 million tonnes mark, and in Amsterdam the increase was 16%. In the hinterland, 6.8 million tonnes of coal (+19%) were transhipped in the port of Duisburg. In Hamburg, 21.7 million tonnes of ore, fertiliser and coal were transhipped, which represents a drop of 2%, and in Dunkirk the volume of coal transshipped (9.7 million tonnes) decreased by 5%.

### Breakdown of coal-based products transport in 2006 by inland waterway in Europe

**Remark:** It should be noted that between 2000 and 2006, the volume of coal transported by inland waterway in western Europe progressed by more than 23% whereas the volumes of other coal-based products decreased by about 20% over the same period.

Regarding imported coal, a distinction is drawn between coal destined for the iron and steel industry and coal destined for power stations. In 2006, coal for power stations represented most of the volume (68%). That year, inland waterways carried 45% of this volume to the German hinterland, where the final destinations are often located immediately on the Rhine. In February and April 2007, the volume of imported coal for power stations in Germany was noticeably less than in the same months in 2006, although the opposite was true for the months of June and November. Overall, Germany recorded an increase in imports of coal amounting to 2.1% in 2007. During the year, imports carried on inland waterways sometimes encountered problems because of low water, while the railway was troubled by strikes in both Germany and France.

Global energy consumption is increasing. At the global level, coal occupies a 30% share in the supply of energy (2006), and there are sufficient reserves for at least 200 years. In the long term, however, a decrease may be expected in Europe (at present coal-fired power stations are already opting for biomass co-combustion). The prospects for the coal sector remain favourable at present: demand for energy continues to rise, and the gradual closure of coal mines in Germany is reinforcing the country's dependence on imports. Moreover, the price of coal remains worthwhile compared with the price of oil, which has increased much more substantially.

*Sources: Union of German coal importers, Port of Rotterdam, Port of Antwerp*

### **2.3.4. Building materials**

#### *General situation of the sector*

This evolution results from the upturn in the construction and public works sector. In Germany in particular, a 5% progress in investments in this sector was expected in 2007. In fact, the activity progressed by 0.6% for construction and 6.6% for public works. At the end of 2007, however, the international economic situation, and more particularly the financial situation, leaves it doubtful whether this sector will continue its upturn in the immediate future. Greater restrictions on credit could have harmful effects on beginning work on new homes, thereby reducing demand for construction materials. Although Germany is currently enjoying a solid economic situation, the question remains open as to the evolution of public works in the other States of western Europe, particularly France. The effects of the economic situation will not however be perceptible until 2008. There is therefore a degree of uncertainty concerning the evolution of demand in this sector.

#### *River transport*

In 2006, the transport of goods in the construction sector made notable progress on the main European routes, except on the Danube, where transport in this sector was relatively stagnant. It may be noted that the volumes transported for this sector progressed by almost 11% on the Rhine, after years of regression.

The first half of 2007 featured an increase of almost 5% in the transport of construction

materials on the Rhine. It was particularly the downstream transport of sand, gravel and cement that progressed, by 14%. It should be borne in mind that the construction materials sector represents more than 20% of the volume transported on the Rhine, the north-south route and the Mittellandkanal. In the Seine Basin area, this segment represents most of the volume transported in containers.

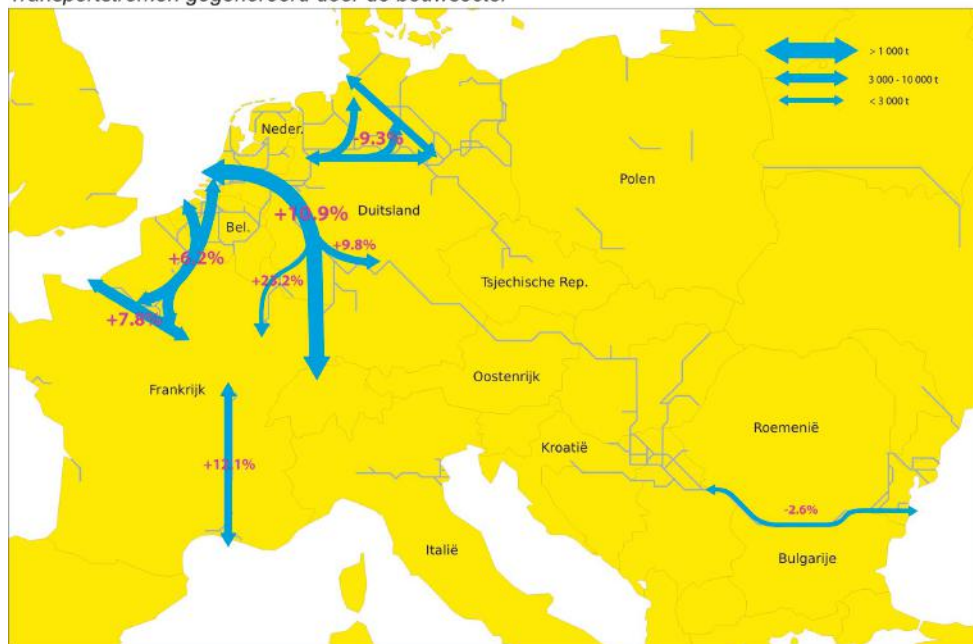

Graph 6

Breakdown of construction materials transported by inland waterway in Europe

## Transportstromen gegenereerd door de bouwsector

### 2.3.5. Container transport

#### *General situation of the sector*

Because of their uniform, solid, stackable nature, the first containers that arrived in Bremen and Rotterdam caused a mini-revolution. More than forty years on, the container has become the symbol of globalisation.

The transport of containerised goods is increasing faster than global trade. Since the container may, in principle, contain any kind of product, it is used currently by nearly every market and industrial sector. On the other hand, it is a demanding market, in which punctuality and flexibility play essential roles. In view of the rate of economic growth, particularly in south-east Asia, the potential for this market remains considerable (according to prognoses, volumes are expected to triple by 2020).

Transport on inland waterways plays an important role in transporting containers into the hinterland (consumer goods), and – perhaps even more significantly – in transporting semi-finished goods from central European industry to the sea ports. At the same time there is a flow of empty containers being returned. 2007 was marked overall by a slight increase in volumes, despite certain regional disparities in the market. In France, an increase of 10% was recorded for the transport of containers into the hinterland, particularly in the Seine Basin area (+30%). This increase was possible because of the increase in automobile production. An increase was also recorded in Strasbourg (where there are plans to increase the capacity for transshipping containers). In Mulhouse, however, transshipments of containers declined. Elsewhere, in Germany services per tkm of transport by inland waterway increased (+1.6%), whereas the tonnages transported decreased (-1.4%). The transport of containers first decreased (-0.6% during the first two quarters), then increased again (according to the most recent data) by 1.2% in September. By comparison, German railways carried 20% more containers in the first half of 2007 compared with the previous year.

#### *On the rivers*

In 2006, the transport of containers on inland waterways decreased by almost 2% by volume on the Rhine and on the north-south route. The reduction continued in the first half of 2007 on the Rhine, although the volumes of goods transported in containers progressed by 9% in terms of tonnage.

This evolution is explained by an increase in the number of full containers (+3%) and a decrease of 9% in the number of empty containers being transported. In June 2007 alone, progress in the volume of full containers transported on the Rhine reached 12%. Behind this evolution lies the fact that sea ports give priority to the transshipment of full containers, which could result in empty containers accumulating at ports in the hinterland. It is possible that other modes of land-based transport may be used to transport them to the sea ports.

On the Danube, container transport is for the moment not very present, but in the Delta this kind of transport is already developing.

Transport flows generated by containers

2.3.6. Transport of oil-based products

The supply of oil to refineries in north-western Europe, as well as exports to the USA, mainly makes use of the ARA ports, and Rotterdam accounts for more than 50% of the market. In the refineries of Rotterdam, as in those of Antwerp and the German ports, crude oil is processed to produce petrol and diesel.

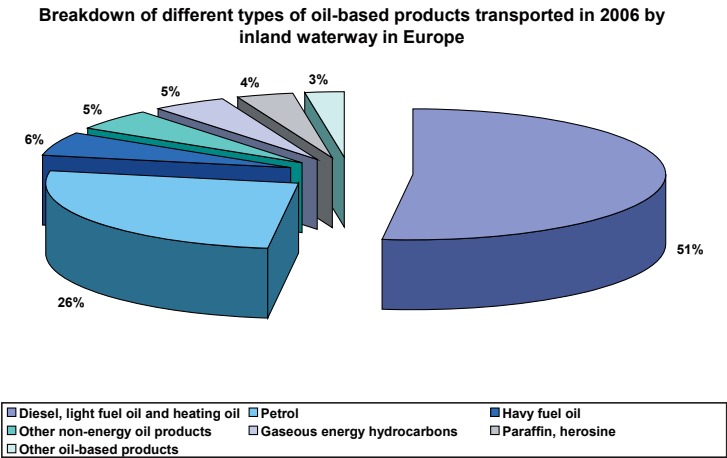

Transport on inland waterways (tanker transport) provides part of the transport from sea ports into the hinterland and transport away from the refineries in the hinterland (particularly in Germany and France) towards to sea ports. In 2006, the volume of goods in the oil sector transported by inland waterway increased by about 1%, as on the north-south route. On the Danube, however, volumes generally decreased, although this depended on the section of river under consideration. During the first half of 2007, the volume of oil-based products transported on the Rhine decreased by 8%, mainly as a result of the increase in oil prices on the market, which produced a maximum deferment of supply purchasing.

In 2007 transshipments of hydrocarbons in Germany stood at about 10% below the level of the previous year. This decrease may be explained by a drop in demand for light fuel oil following the mild winter, and the use of other alternative sources of energy (gas). The volumes of diesel and petrol transported remained stable. There have been periodic upswings in demand on the market. Thus during the second quarter there was strong demand for petrol to be transported to the USA. The price of crude oil and, as a result, the purchase prices of petrol, diesel and light fuel oil increased constantly throughout the year.

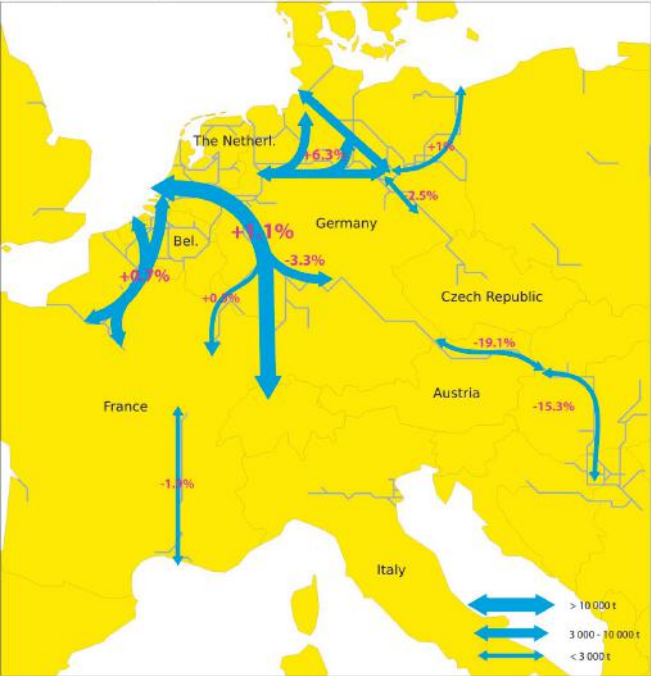

This is a global approach to the oil sector, which may give a slightly different image of the market than the above text, which refers to the detailed evolution of the various products, and also gives first impressions for 2007.

Source: Port of Rotterdam, Port of Antwerp, Mineralöl Wirtschaftsverband

Graph 7

Transport flows generated by oil products

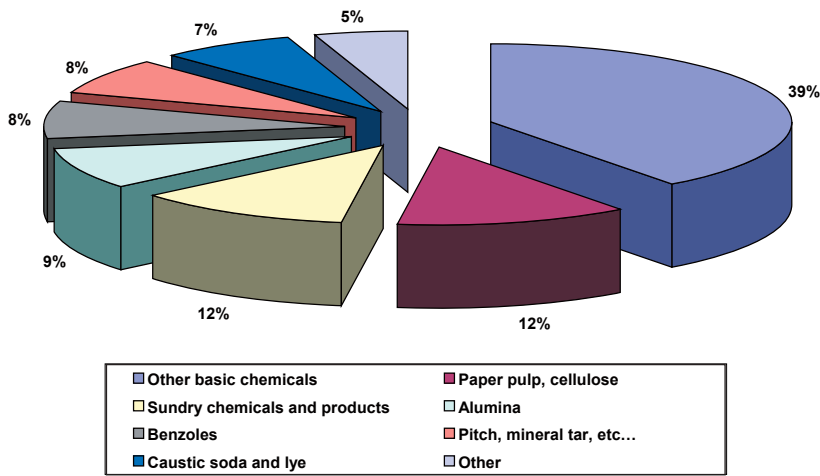

2.3.7. Chemicals sector

Demand for chemicals remains sustained, both inside Europe and globally. In Europe, this demand is met by local production and by imports. The chemicals sector saw very good results in 2007, with European production increased by about 5.5%. The forecasts for 2008 are more modest, particularly because of the more uncertain general economic situation further to the events of recent months in the financial sector in the United States.

Graph 8

Breakdown of chemicals transported in 2006 by inland waterway in Europe

While in 2006 the transport of chemicals progressed by 1.9% on the Rhine and by 8.9% on the north-south route, it progressed on the Rhine by almost 9% in volume and by 4% in services during the first half of 2007 compared with the first half of 2006. This evolution is explained by the resumption of growth in this sector after a slight downturn in 2006. The continuation of this increase in the volume transported in the coming months depends on the general evolution of the European economy, but at the start of 2008 the sector itself is in a growth cycle.

Transport flows generated by chemicals

## 3. Transshipments in ports and the modal split of inland waterways

### 3.1. Sea ports

Because of their strategic position and their depth, Ara and North-See ports offer good access to a part of the European market where a dense population consumes and produces intensively. In 2006, the ports between Hamburg and Le Havre saw their transshipments in tonnes increase by 5.5% and transshipments of containers, measured in TEUs, increase by 9.5%. The ports of Antwerp and Rotterdam, which are generally used as a benchmark for transport on inland waterways, made less progress. In 2007, European sea ports recorded growth across the board, with the container market once again standing out in front of the other sectors. The major sea ports (Rotterdam, Hamburg and Antwerp) saw further increases in transshipment volumes compared with 2006, particularly as the growth rate for the container sector was between 12% and 14%. Evolution was similar in all the ports. In terms of container volume, Hamburg is China's most important partner in commercial trade, and Antwerp is the most important partner of the USA and Singapore. For intra-European transport, Rotterdam holds a very strong position, particularly in relations with the United Kingdom. In other – smaller – European sea ports, the growth in container volumes has sometimes been even higher. Even so, it should be borne in mind that it is easier to achieve a high percentage of growth when starting from a low figure, which is the case of Amsterdam, for instance. The large sea ports have meanwhile become much more than transport hubs; they have become industrial and port complexes incorporating handling and business activities.

The table below describes the evolution in container volumes (TEUs) handled in these sea ports.

	Hamburg	Bremen	Amsterdam	Rotterdam	Antwerp	Zeebrugge	Dunkirk	Le Havre	Total
<b>2000</b>	4248	2737	53	6094	4082	965	148	1464	<b>19791</b>
<b>2001</b>	4689	2915	48	6096	4218	876	151	1525	<b>20518</b>
<b>2002</b>	5374	2999	45	6506	4777	959	161	1720	<b>22541</b>
<b>2003</b>	6138	3191	38	7144	5445	1013	161	1980	<b>25110</b>

Source: Port of Rotterdam

Over the 7 years we may observe a 73% increase in the transshipment of containers in the main sea ports of western Europe, which corresponds to average progress of 9.6% per year. Alongside this, the volumes transported by inland waterway in Germany, a country that is located at the centre of the European river network, only progressed by about 53%, i.e. an average of 7.4% per year. This difference undoubtedly reflects a regularly declining market share for transport on inland waterways in Europe.

## ROTTERDAM

In 2006, the port of Rotterdam recorded relatively slight growth in its transshipments, limited to just +1.7%, with 378 million tonnes, mainly as a result of the increase in the volume of containers (+4.3%) and coal (+3%), whereas for example the volumes of metal ores and scrap declined. 2007 was an exceptional year for the port of Rotterdam. This leading European port transshipped more than 400 million tonnes and handled more than 10 million TEU containers. Trade with Asia is certainly a driving force for growth in the container sector, but most of the goods handled were from Europe. For 2007, taking all goods together, the volumes transshipped increased by 6.4% and incoming and outgoing containers increased by 12% and 9% respectively. The acceleration in this growth in volumes was particularly marked in the second half of 2007. Transshipments of plant oils decreased, although those of ethanol and biodiesel increased. The transport of metal ores and scrap recorded growth. The decreases only concerned crude oil (-2%) and other bulk goods (-3.5%). The port's prospects are good: according to forecasts, growth will generally be sustained over the coming years. This trend will be amplified for the containerised goods sector, which should see considerable development. This applies equally to intra-European ("short sea") traffic and to intercontinental ("deep sea") traffic. Rotterdam is beginning to reach the limits of its capacity, for both containers and dry bulk goods. The situation of dry cargo is due to the increase in imports of coal to Germany, resulting from the gradual closure of the country's mines. It has been established that an extension would be worthwhile. This is why a short-term increase in transshipment capacity has been scheduled (Delta Barge Feeder and Euromax terminals). Other investments are announced in the longer term, including the scheduled development of the Tweede Maasvlakte intended to meet the strong demand for additional transshipment capacity. Of the 1000 hectares included in the project, about 625 will be earmarked for container terminals, which represents a considerable extension. The allocation of Tweede Maasvlakte plots is currently in hand and the Port of Rotterdam would like to devote most of the extension to rail and inland waterway transport.

*Source: Port of Rotterdam*

## ANTWERP

In 2007, the volumes transshipped overall increased by 9% compared with 2006 (i.e. a growth rate double that recorded in 2006, thereby reaching 167 million tonnes). In 2007, transshipments accounted for 182.9 million tonnes in all. The volume of containers transshipped represented 8.2 millions TEUs, i.e. an increase of 14% for this important sector (the figure for TEUs was only 7 million TEUs in 2006, and 6.5 million in 2005). This means that Antwerp remains the third most important port for containers in Europe (after Rotterdam and Hamburg). In this sector, North America is a trade partner of capital importance. The Deurganckdok with its capacity of 6.4 million TEUs is designed to cope with the strong growth expected over the coming years. Maintenance work on locks and the widening of the Escaut will ensure better accessibility for Antwerp from the sea front. Transport on inland waterways also played an important role in 2007 in carrying goods, mainly towards the Netherlands (44%), but also inland to the rest of Belgium and to Germany (24% in both cases). Transport on inland waterways accounts for the transport of about one-third of the volume of containers carried out of Antwerp into the hinterland. This mode of transport also has an important share of the market for incoming and outgoing oil-based products (30% in 2007), chemicals (14%), and containers (26%). Growth of 9% has been recorded for the transport of containers.

*Source: Port of Antwerp*

## HAMBURG

In 2006, the volumes transshipped increased by 7.3%, with the total reaching 135 million tonnes. For containers, with 8.9 million TEUs transshipped, i.e. an increase of 10%, Hamburg again beat its own record in 2007. Total transshipments amounted to 140 million tonnes (+4.1%), including 9.9 million TEUs handled, representing progress of +11%. Although China and India are the main exporters overall, Hamburg also had a lot of commercial relations with nearer neighbours (Baltic Sea). Contrary to these very favourable results, the transshipment of bulk goods declined in 2007 by 2.4% (ore, fertiliser and coal). Hamburg has set itself the target of breaking the ceiling of 10 million TEU containers next year, hoping to overtake Rotterdam in this sector in the next ten years. The fact that the port of Hamburg is the closest to the new EU Member States in eastern Europe and that it has strong links with Russia where the economy is thriving would be major advantages for the port. One prior condition would consist of improving its access (and its depth) on the sea side. In this respect, preparations are already in hand. Since 2007, the Port of Hamburg has been quoted on the stock exchange. The financial resources released in this way are intended, *inter alia*, to improve the infrastructures in the container transshipment sector. Rail transport is considered to be a powerful means of decongesting the roads (18% of containers in 2007). Because of this, the Port of Hamburg has become the most important rail platform in Europe.

*Source: Port of Hamburg*

## AMSTERDAM

The overall growth rate of transshipments in the sea ports of Amsterdam – including Zaanstad, Velzen/Ijmuiden and Beverwijk – was 1.5% in 2007, an increase from about 84.4 million tonnes to about 85.7 million tonnes. For Amsterdam alone, the figure is 4.6%. The transshipment of TEU containers increased by 370 000, i.e. +21%, after volumes more than tripled in 2006 with the opening of the new terminal. The number of empty containers transshipped also increased by 109%, reaching a figure of 55 601 TEUs. The Ceres container terminal has not yet reached half its maximum capacity (a maximum of 1 million TEUs). The transshipment of vehicles increased by 30%, from 214 685 to 279 000. Transshipments increased by about 12% in 2006, particularly because of oil-based products and containers, which progressed by 370% compared with 2005.

*Source: Port of Amsterdam*

## LE HAVRE

The total volume of transshipments reached 74.8 million tonnes in 2006, which represents a drop in the order of 1.6% compared with the previous year. For containers, the volume transshipped was 3% more than in 2005. The modal split of transport on inland waterways for transport into the hinterland was 7% in 2006. It was a good year for Le Havre, with 6.6% growth in transshipments overall, reaching almost 80 million tonnes, and an increase of 25% in the container sector (a total of 2.6 million TEUs). The opening of a container terminal has contributed to these impressive results. For dry bulk (coal), the results also showed an increase of almost 31%, but the transport of oil-based products recorded a decrease (temporary decrease in refining capacity).

*Source: Autonomous Port of Le Havre*

## BREMEN

Bremen, the German port transited by most automobiles, recorded a 6.3% increase in transshipments in 2007 compared with 2006, reaching 69 million tonnes. For containers, the

increase was 10.4% (a total of 4.9 million TEUs). Liquid bulk (a relatively small sector), on the other hand, recorded a drop of -32%. In 2006, the volumes transshipped in this port amounted to 65 million tonnes, which represents a progression of 16% compared with 2005.

*Source: Bremenports*

#### **DUNKIRK**

In 2006, the volume of transshipments in the port of Dunkirk reached 56 million tonnes, which represents a progression of 6%. Whereas in 2006 the volume of containers transshipped increased by a further 0.5% compared with 2005, with 205 000 TEUs, Dunkirk was the exception in the ports between Hamburg and Le Havre in 2007, with container volumes down by 4% to 197 000 TEUs. Despite that, the overall volume of transshipments increased by 1% in 2007, to 57 million tonnes.

*Source: Port of Dunkirk*

#### **ZEEBRUGGE**

During 2006, the volumes transshipped amounted to 39 million tonnes, equally divided between incoming and outgoing volumes. This corresponds to a rate of progress of 12% compared with 2005. In 2007, 42.3 million tonnes were transshipped in this port, which corresponds to an increase of 7.3%. The transshipment of containers increased by 24%, to reach 2 million TEUs in 2007 (in tonnes, this represents growth of 11%). The creation of new lines is the reason for this substantial increase. The market for vehicles remains the strong point of this port, where transshipments of liquid goods has decreased.

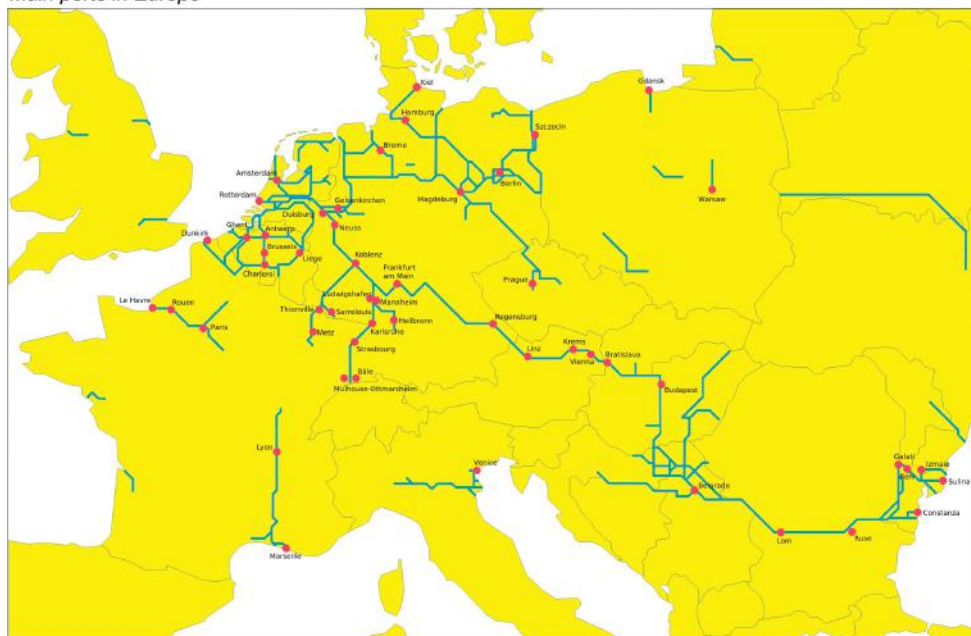

*Source: Port of Zeebrugge*

#### **WILHELMSHAVEN**

This is currently the third most important port in Germany by volume handled (2004: 45 million tonnes per year). It acts as a bridge to the Scandinavian countries, the new Member States of the EU and the Baltic states. The JadeWeserPort that is currently under construction, with a depth of 18 m and a wide area (170 ha), will boost container transport in the region. According to forecasts, capacity will reach 2.7 million TEUs in 2010.

*Source: Port of Wilhelmshaven*

## Main ports in Europe

### 3.2. INLAND PORTS

Source: Internet sites of the ports, forecast data

The inland ports on the European mainland constitute a network of sites for regional transshipment that is often trimodal, generally serving several markets. For 2006, the figures for transshipments published by the inland ports showed evolutions unlike those for 2005, with for example +13% for Frankfurt and the opposite (-7%) for Basle. For the container sector, reference could be made to Frankfurt with +40% and Mulhouse-Ottmarsheim with -27%. For all the markets as a whole and all the modes of transport, 2007 was, like 2006, a year of growth. Evolution within the various partial markets may have a considerable influence on the volumes to be transported. Thus in 2007 transshipments in Liège increased by 8%, more particularly as a result of the resumption of operation of its blast furnaces. Frankfurt-am-Main recorded an increase in transshipments of coal, construction materials and recycled materials, and more particularly exports of scrap metal, in response to demand from China. Basle recorded an increase in transshipments overall (+5.3%) (more particularly for containers), even though oil-based products dropped. Karlsruhe was an exception in this context, since transshipments there fell by 10% in 2007, after recording an increase of more than 9% in 2006.

Although growth in container transport is less marked on the Rhine than in the sea ports, there are many projects under consideration aimed at increasing capacity to transship containers. In Frankfurt-am-Main, the area of the transshipment site will be increased by 4000 sq.m., taking its maximum capacity to 100 000 TEUs in 2010. The new Hanse-terminal container terminal (including a logistics centre) in Magdeburg was opened in May 2007. According to forecasts, its transshipment capacity will reach 33 000 TEUs per year. It should however be noted that

in all these cases, rail will also play an important role. The fact that the expansions do not only concern the Rhine is illustrated by the following examples. In Vienna, which recorded an increase of 23% in the volume of containers transshipped in 2007, for all modes taken together, annual capacity will be increased to 400 000 TEUs per year from the end of 2008. These volumes will essentially be divided between road and rail. To reach this capacity, the existing trimodal Wienercont. Terminal is to be modernised. The Enns trimodal logistics centre which opened in 2007 has stimulated container transport with its capacity of 250 000 TEUs per year (153 000 TEUs were transshipped in 2006, i.e. 20% more than in 2005).

#### *DUISBURG*

Compared with 2005, the volumes transshipped in the port of Duisburg progressed by 4.2% in 2006, giving a volume of 51.3 million tonnes. The container sector achieved a similar growth rate, reflected by a volume of 357 000 TEUs for transport on inland waterways. Transshipments in the port of Duisburg reached the level of 55 million tonnes, which corresponds to an 11% increase, to which transport by inland waterway only contributed 4%. Rail (shuttle service with Antwerp) is playing an important role in the development of the port. The transport of coal occupies a prime position here, but Duisburg is also one of the top 100 container ports in the world, recording an increase of 14% in 2007 (after more than 4% in 2006), to reach the level of 900 000 TEUs, nearly all of which has however been of benefit to rail transport. In 2007, a new container gantry was commissioned and preparatory work is in hand for a substantial new extension to capacity for the transshipment of containers and the associated logistics.

#### *MANNHEIM*

Compared with 2005, transshipments in the port of Mannheim fell by 1.9% to the level of 8 million tonnes in 2006. Even transshipments of containers fell by 12%, to the level of 120 000 TEUs. In 2007, however, 5% growth was recorded, for a total of 8.3 million tonnes. In this favourable context, we may observe for the second year running a drop in transshipments of containers, which fell again in 2007 by a further 10%, reaching the level of 108 066 TEUs. Although the accident in Cologne (in March 2007) caused an unexpected drop in volumes, other causes of a more structural nature have also been contributing factors. The results for 2007 are nevertheless globally the best since 1988. The commissioning of a container terminal, which will increase transshipment capacity, is intended to anticipate growth in waterway transport's share of the market. At the same time, the dock will be lengthened and the rail network extended by two additional lines.

#### *COLOGNE*

2006 showed a general drop in transshipments by 4.5% to 15.6 million tonnes, whereas transshipments of containers towards transport on inland waterways increased by 21% to reach the level of 114 481 TEUs. In 2007 the rate of growth in transshipments was 3.2%, i.e. a total of 11 million tonnes, 12% of which was the container sector, which transshipped 574 000 TEUs. Container transshipment capacity is also being expanded at the moment. Rail transport, which has a market share of 18% at this port, also plays an important role here.

## PARIS

With 22 million tonnes of transshipments each year, Paris is the second most important inland port in Europe in terms of volume, after Duisburg. The container terminal in Gennevilliers concentrates more particularly on container transshipments. In 2006, almost 80 000 TEUs were transshipped, which represents growth of almost 10% compared with 2005. The Paris region is anticipating 120% growth in volume over the next 15 years, which would be in keeping with the considerable extension of capacity at the port of Le Havre, and it is with this in mind that there are plans to extend the terminal in Gennevilliers. While it is intended that Gennevilliers should remain the focal point for container traffic in Paris, there are also plans to set up a network of new trimodal terminals on the outskirts of Paris.

## BASLE

In 2006 the port of Basle saw the volume of dry goods transshipped on the river progress by 5.8%. With 88 030 TEU containers transshipped, the record achieved in 2004 (85 254 TEUs) was broken, reflecting a new growth phase. Incoming oil-based products, however, dropped back by 17.1%; this was due not only to the very high price of oil until December, but also to structural causes.

2007 was also a good year for transshipments, with a new record for containers (104 366 TEUs, i.e. an increase of 21.3% compared with 2006). More generally, transshipments in the port of Basle progressed by 5.3%, thereby reaching 7 108 230 tonnes, despite a 10% drop in demand for oil-based products. It was possible to achieve these favourable results not only because of a favourable general economic context, but also because of water conditions that may be qualified as good in relation to the figures for previous years.

## Chapter 2

### Analysis of offer of transport capacity

Observation of the evolution of the offer of transport on the European market, which is measured mainly on the basis of capacity available on the market, remains a difficult exercise in view of the absence of harmonisation of the method of listing vessels and keeping national records. In the present situation it appears at first sight, in fact, that the number of vessels being scrapped is very limited, although there is no means of checking this. At the same time, certain elements are known concerning transfers with neighbouring countries and new constructions coming onto the market in the course of the year. This procedure allows, as far as possible, an update of the image of active capacity.

#### New capacity on the market

Observation of new arrivals on the market points to a clear drop in the number of new vessels commissioned in 2007 compared with 2006. This needs to be seen in context, since at the start of 2008 not all the registers have yet been updated to include registrations made at the end of 2007.

It should be noted that it is difficult, in the present administrative context, to obtain comprehensive data for most of the Rhine States and even more difficult for the Danube and eastern European States. For this reason, the data set out below refers only to the fleets of western Europe.

#### Breakdown by size of new vessels commissioned

Type of vessel	2006		2007 (provisional)	
	quantity	% of capacity	quantity	% of capacity
<b>Self-propelled barge</b>	<b>41</b>	<b>100%</b>	<b>10</b>	<b>100%</b>
0 - 1999 t	5	5.1%	1	3.7%
2000 - 2999 t	9	20.7%	2	19.2%
+ 3000 t	25	74.2%	6	77.1%
not known	3		1	
<b>Non-motorised barge</b>	<b>25</b>	<b>100%</b>	<b>13</b>	<b>100%</b>
0 - 1999 t	15	25.6%	1	4.2%
2000 - 2999 t	6	61.2%	10	76.3%
+ 3000 t	1	13.2%	2	19.5%
not known	4		0	
<b>Self-propelled tanker barge</b>	<b>35</b>	<b>100%</b>	<b>13</b>	<b>100%</b>
0 - 1999 t	7	12.7%	3	14.7%
2000 - 2999 t	7	19.2%	2	17.1%
+ 3000 t	15	68.1%	5	68.2%
not known	6		3	

Source: IVR + national sources

For the state of the fleet at the end of 2006, elements have been made available by the IVR which provide figures for the active fleets of most of the Danube and eastern European fleets. At the same time, the lack of data on the Dutch fleet – which accounts for more than 60% of potential dry cargo transport capacity and more than 50% of potential tanker transport in western Europe – makes it necessary to estimate these fleets.

Graph 9

New capacity on the market

It should be noted that 44 tanker vessels are expected to be commissioned in 2007, according to the professionals concerned. For the administrative reasons mentioned above it will not be possible to check this information in the next publication.

There may, however, be other explanations than the hazards of statistics for the apparent decrease in the number of new vessels.

It should indeed be borne in mind that the shipyards are working at full capacity, which justifies the order deadlines. In addition, the cost of shipbuilding has increased considerably in recent years, as the result of increased prices for steel and labour. Bank interest rates have also risen by more than one point in the space of a year. These two factors have without doubt had an effect on decisions whether to invest in new vessels, even though the market looks promising in terms of prospects for demand, particularly for the transport of dry cargo.

Apart from certain hazards in statistics, it can be seen that the western European fleet is tending to grow. Tanker transport has seen the highest rate of progress, at +5% in 2006 compared with +1.3% for dry transport.

Graph 10

### Evolution of the fleet

Remark: In view of the fact that data for the Danube and Czech fleets only became available for the first time in 2006, this graph – which is intended to show the evolution of capacity on the market over the years – does not incorporate these elements. It will be possible to do so in future publications, when there is data available for observation over at least two years.

Remark: In the statistics in the appendices, pushed/towed barges are not included. There are still some 170 of these in western Europe, which represents about 3% of capacity, and their number continues to fall each year. Since they are not generally used very intensively, their impact on global offer appears to be negligible.

In terms of the structure of the fleet, the average capacity of vessels (self-propelled and non-motorised barges taken together) has increased by about 2% for dry transport and tanker transport.

This evolution in fleet structure is due to the commissioning of new vessels that are mainly large in size, whereas for tanker transport there is at present no comparable withdrawal of old vessels. For dry transport, although capacity is increasing, the number of vessels is falling. This trend may be explained by sales of small vessels to other countries outside the Rhine area and to assemblies of two vessels.

## **Fleets on the Danube and in eastern Europe**

Although the elements we have available allow us to estimate capacity for dry transport at about 3% of European capacity, the proportion of tanker transport capacity is very slight. It should however be noted that the Hungarian and Austrian fleets have not been taken into account because of the lack of exact data. For this reason a detailed analysis of the structure and evolution of these fleets will be included in a later publication, when it has been possible to incorporate these elements.

## Chapter 3

### Water conditions

#### 1. Water conditions and operating capacity

As the observation of water conditions is important in economic terms, the values are not only indicated on a daily basis and in centimetres, but are also converted into values for possible draught, determining the theoretical loading capacity. The graphs below show the figures for the scales at Kaub for the Rhine and Hofkirchen for the Danube.

For goods vessels of varying dimensions, this gives the following loading capacities according to draught.

Loading capacity according to vessel dimensions	Draught				
	1.50m	2.00m	2.50m	2.80m	3.50m
L135.00 X W11.45	750t	1 475t	2 225t	2 600t	3 700t
L110.00 X W11.40	600t	1 200t	1 800t	2 100t	3 000t
L85.00 X W9.50	570t	930t	1 350t	1 350t	1 350t
L67.00 X W8.20	420t	670t	1 000t	1 000t	1 000t

*L: length*

*W: width*

*Source: VBW (WESKA)*

These figures show clearly the effect of water conditions on the offer of transport. Periods of low water have a greater effect on larger vessels.

## 2. Water conditions on the Rhine

Graph 11

Source: German national hydrological institute (Bundesanstalt für Gewässerkunde)

### Number of days below draught limit

Draught	less than 240	of which less than 180
2005	72	0
2006	93	0
2007	201	0

### Indexing water levels noted at scales

To be able to compare variations in water levels recorded at the scales and variations in freights, it is necessary to index the main scale for the waterway concerned. Indexing calculations should, however, be based on quarterly values. The annual average for 2004 could be taken as the base index of 100.

At the Kaub scale, the figure for the annual average for 2004 to be used as the base index of 100 is 188 cm.

The index values may also be expressed in monthly values which may be compared with other variables.

Graph 12

Source: German national hydrology institute (Bundesanstalt für Gewässerkunde)

## Study of the situation in 2007

The water conditions on the Rhine did not indicate any period of low water in the first half of the year or at the end of the summer of 2007. There was even a short period of high water. Under these conditions, it was possible to operate transport capacity at a relatively optimum level until the summer. During the autumn, there were more important fluctuations in the water conditions. Navigation was even stopped for a few days in some sectors, before a period of low water occurred in September and continued for several weeks. At the end of the year, water conditions were very abundant. Overall, the water cycles in 2007 were the opposite of those in previous years, when there was low water during the summer and at the end of the year.

### 3. Water conditions on the upper reaches of the Danube

The method used for studying the water conditions of the upper reaches of the Danube is the same as that used for the Rhine. An index is calculated with reference to the average year of 2004.

Graph 13

Source: German national hydrology institute (Bundesanstalt für Gewässerkunde)

#### Number of days below draught limit

Draught	less than 240	of which less than 180
2005	245	68
2006	206	48
2007	60	0

On the upper reaches of the Danube, where water conditions at times constitute the most important factor limiting transport on inland waterways, the water conditions in 2007 were relatively favourable for river traffic compared with 2006 and more particularly 2005. During 2007 the draught was never less than 180 cm, and it was only less than 240 cm for 20% of the year. There was no flooding prejudicial to navigation.

Graph 14

Source: German national hydrology institute (Bundesanstalt für Gewässerkunde)

#### 4. Water conditions on the Elbe

The rate of flow of the Elbe depends directly on precipitation upstream. Unlike the Rhine, its flow is not fed periodically by the melting of snow and glacier ice in the Alps, and as a result its water conditions are relatively volatile, and there are frequent periods of low water that are prejudicial to navigation. This element is currently hindering the development of transport on inland waterways, with vessel operators preferring to work on the Mittellandkanal and its connected network, where transport is much more regular.

It is a feature of the Elbe that its water conditions are cyclical – they are generally sufficient, and even over-abundant, in the first half of the year, with a recurrent tendency to periods of low water in the autumn.

Water conditions in 2006 were relatively abundant, and there was even a period of high water when navigation stopped for eight days. In 2007, however, the period of low water began at the end of May and continued throughout most of the second half of the year.

**Remark:** Details are not given here for the Moselle, Main and Neckar, since their water conditions are relatively linked to those of the Rhine, of which they are tributaries.

Water levels on the Elbe at Magdeburg

## Conclusions and forecasts

Although overall the market for transport by inland waterway stood up well in 2006 and 2007, with significant progress in places, it has to be said that the market share is not evolving at the same rate, and more particularly that road transport remains out ahead.

Rail also seems to be developing faster than transport on inland waterways, in both the States of central and eastern Europe and the western part of Europe.

Indeed in most of the segments of bulk goods transport, such as ore, coal, construction materials and oil-based products, transport on inland waterways occupies a very strong competitive position, with market shares close to the maximum possible in view of the characteristics of the routes and occasional contracts. Improvements could still be made in these segments if the infrastructure were adapted in such a way as to allow transport on inland waterways to be fully competitive in terms of reliability, capacity and accessibility.

For other segments, the potential for waterways transport to make progress depends primarily on the efficiency of the services offered throughout the logistics chains involved. This concerns the market for agricultural and food products, chemicals and container transport.

### Regional markets

2006 showed progress in traffic on the north-south route and on the Rhine, while there was a decrease in volumes transported on the east-west route and on the whole of the Danube.

### Containers sector

In this key sector for transport on inland waterways, 2006 and 2007 were marked by stagnation, despite a significant increase in traffic in and out of the sea ports. Near the terminals, the congestion of the interfaces between sea and river transport seems to continue. In Rotterdam in particular transport on inland waterways has to cope with unfavourable operating conditions, which are reflected in a reduced market share. Rail transport also seems to be well on the way to strengthening its competitive position, with the introduction of several new regular services, even towards "wet" destinations.

### Evolution of the main goods

The development of the transport of the various types of goods carried on inland waterways varies in the different regions. While some types of transport, such as the transport of raw materials for the iron and steel industry, fell in Europe in 2006, this evolution is mainly explained by the policy of stockpiling in anticipation of a period of less demand in Europe.

Transport in connection with agriculture is cyclical, and is also linked to the policy of stockpiling and world prices. Thus the drop recorded in 2006 was followed by a period of growth in 2007.

As this was a period of general economic growth, the volumes of other types of goods carried also increased in 2006, and the provisional figures available to date indicate that this trend continued in 2007.

### Evolution of the fleet – new vessels

Despite the difficulties still being encountered in the registration of fleets, the data available indicates an increase in transport capacity in western Europe that was reflected by an increase in average vessel tonnage. This increase in average tonnage is the result of investments,

reflected by the contribution made by new vessels coming onto the market or the lengthening of existing vessels. It should be borne in mind that this new capacity mostly goes hand in hand with operation of above-average intensity.

In this context, the data available shows a dynamic degree of investment in both dry transport and tanker transport. While the increase in capacity for dry transport seems to be continuing to evolve on a par with demand, tanker transport remains open to question. In this segment it is primarily a matter of replacing part of the fleet in order to meet present and future technical demands.

### **Water conditions**

2006 and 2007 did not see any extreme situations in terms of water conditions. On the Rhine, transport was possible under satisfactory conditions from this point of view. On other waterways such as the Elbe and the upper reaches of the Danube, the water conditions and their irregularity continue to constitute a limiting factor for the development of transport on inland waterways.

### **General economic situation and impact on demand in 2008**

In 2006 and 2007, transport on inland waterways had the benefit of an extremely favourable general economic situation in Europe. At present, despite the uncertainties caused by the disturbances in the banking sector in the United States, there is not at the moment any real sign of any slowing down in industrial activity in Europe that could be likely to potentially reduce demand for transport in 2008.

## Glossary

**20-foot Equivalent Units (TEUs):** Unit of measurement for registering containers according to their dimensions and for the description of the capacity of container vessels and terminals. One ISO 20-foot container (20 feet long and 8 feet wide) corresponds to 1 TEU.

**ARA ports:** Abbreviation for the three major European ports of Amsterdam, Rotterdam and Antwerp.

**Downstream navigation:** navigation downriver

**Downstream:** Refers to the part of an inland waterway located between a given point and the embouchure or confluence.

**Draught:** Height of the immersed part of a vessel; thus draught affects the loading level.

**Dry hold:** Used for the transport of dry cargo.

**Freight:** Refers to goods being transported or the price of transport.

**Handling:** Transshipment of goods from one means of transport to another.

**Hold:** Compartment covering the larger part of a commercial vessel, for the storage of cargo to be transported.

**Inland navigation / inland waterways transport:** Transport of goods or persons on board a vessel intended for transport on a given network of inland waterways.

**Inland waterway:** Navigable inland waterways that may be used with a normal load by vessels with a minimum deadweight of 50 tonnes. Inland waterways include navigable rivers, lakes and canals.

**Offer of transport or of capacity:** Total loading capacity of the available fleet, expressed in tonnes.

**Production/yield:** The notion of production/yield as used in this publication is intended to define in index form the activity of inland waterways transport, taking into account a given level of demand and the freight rates applied on the market.

**River/sea transport:** Transport of goods on board a river/sea vessel (seagoing vessel designed for use on inland waterways), carried out entirely or partly on the inland waterways network.

**Service:** Refers to the service of the transport of goods, expressed in tonnes/kilometre.

**Tanker hold:** Used for the transport of cargo in tankers.

**Tonnes/kilometre (Tkm):** Unit of measurement for transport services, corresponding to the transport of one tonne over one kilometre of an inland waterway. Determined by multiplying the volume carried in tonnes by the distance travelled in kilometres.

**Transshipment:** Unloading of a cargo from one seagoing freight vessel and loading onto another seagoing freight vessel, even if the cargo has remained on land for any length of time before the transport continues.

**Upstream navigation:** Navigation travelling upstream.

**Upstream:** Refers to the part of an inland waterway located between a given point and the source.

**Water conditions:** Height of the water in a river or canal, in cm.
